Tumor-associated osteopontin expression: clinical and molecular markers in recurrent, metastatic and refractory ovarian carcinoma. Osteopontin (OPN) is a cytokine-like secreted glycoprotein that interacts with a variety of cell-surface receptor integrins and is frequently expressed in various tumors. We have previously observed OPN expression in adenocarcinomas and neuroendocrine tumors from several organs and a high incidence of metastases in colorectal and neuroendocrine tumors. In the current study we used anti-OPN immunostaining (anti-OPN-IS) in 324 ovarian carcinomas to evaluate whether: (1) OPN expression correlated with clinicopathologic features or lymph node involvement, (2) OPN expression could serve as a marker of early recurrence and metastasis, and (3) down-modulation of OPN by antisense therapy inhibited in vivo tumor growth. Tumor tissue from patients with different pathological stages, grades, lymph node involvement and distant metastasis demonstrated OPN-IS in the plasma membrane. OPN expression correlated with some histopathologic features, including the existence of tumor foci in the peritoneum and the presence of ascites. In contrast, there was no association with tumor grade, serous or mucinous histology, presence of endometriosis, or expression of CA125, CEA or CA19-9. OPN-IS was found in 90% of all ovarian carcinomas and in all of the epithelial components (69% of adenocarcinomas, 78% of mucinous, 100% of serous and 18%

of undifferentiated carcinomas). OPN-IS was associated with locoregional recurrence and distant metastases. In a subset of patients who had a complete clinical response to paclitaxel/cisplatin chemotherapy, the mean time to relapse was significantly lower than in patients with an initial partial response. These findings suggest that OPN may promote tumor growth and metastasis and that OPN-targeted therapy may be beneficial in some patients with ovarian carcinoma.
